Strange as it may seem, early germ theorists could tell us a lot about today's attitudes toward climate change.

While researching for a new book about the [history of emerging infections](#), I found many similarities between early debates over the existence of microbes and current debates over the existence of global warming.

Both controversies reveal the struggles of perceiving an unseen threat. Both reveal the influence of economic interests that benefit from the status quo. But most importantly, both reveal how people with different beliefs and interests can still agree on key policies and practices for tackling a global problem.

### **What you can't see might hurt you**

Seeing is believing, and until the mid-19th century, it was very difficult to see the tiny organisms responsible for our so-called "fever" diseases.

Although the indirect evidence was compelling, many people remained skeptical of "animalcules" — as microorganisms were once called — until [the microscope was sufficiently developed](#). Even then, [acceptance was gradual](#). The once-dominant ideas about disease-causing gases, called miasmas, persisted for several decades before most people acknowledged that the fevers had a living cause.

Climate change presents similar challenges of visibility. Although everyone can see and feel the weather, it is often difficult to observe its [larger patterns and longer trends](#) without the aid of technical charts.

## Global temperature anomaly (compared to 1951-1980 average, in degrees Celsius)

## Carbon dioxide emissions (in parts per million)

## Global sea level rise (change in millimeters)

Charts show how global temperature, carbon dioxide emissions and sea level have risen over time. [NOAA, NASA, Goddard Space Flight Center/PO.DAAC](#)

Even when people acknowledge the bigger picture, the case for human responsibility is complicated by the fact that the [carbon emissions](#) from our engines, like the germ infections within our bodies, are unseen by the naked eye. It is hard to achieve human solutions when the evidence of human cause is invisible.

## Economics can outweigh evidence

Adding to these challenges, economic interests often confound scientific recommendations.

In the case of germ theory, early recommendations to prevent the spread of infection included [reinstating quarantines](#) at shipping ports and border crossings, thus impeding the international flow of trade.

In the case of climate theory, recommendations to slow global warming include [reducing the consumption of carbon-based fuels](#), thus reducing the flow of oil. These

strategies can threaten livelihoods as well as profits, so it is not surprising to find [labor unions divided over green initiatives](#) and energy executives spreading [misinformation about climate science](#).

## **Beliefs and interests need not coincide**

But people's beliefs and interests need not align if everyone finds some benefit in the recommendations.

This was the case in the latter decades of the 19th century, when germ-denying surgeons nevertheless adopted [the antiseptic techniques of Joseph Lister](#).

They did so mainly for the practical reason that their patients fared better under the new methods. But if an explanation was needed, many of these die-hard skeptics claimed Lister's methods prevented the [transmission of miasmas](#) rather than living organisms.

Responding to these claims, Lister stated:

"If anyone chooses to assume that the septic material is not of the nature of the living organisms, but a so-called chemical ferment destitute of vitality ... such a notion, unwarranted though I believe it to be by any scientific evidence, will in a practical point of view be equivalent to a germ theory, since it will inculcate precisely the same methods of antiseptic management."

Lister was more concerned with saving lives than winning arguments. As long as the surgeons adopted his methods, Lister cared little about their justifications. When it came to preventing infection, it was the behaviors rather than the beliefs that counted.

## Changing behaviors through complementary interests

The same could be said for global warming: Changing behaviors is more important than changing beliefs.

Case in point, there is a large and growing [environmentalist movement among evangelical Christians](#). Organizations such as [Green Faith and the Creation Care Task Force](#) cite Biblical scripture to promote environmental stewardship as a sacred duty.

While many of these groups acknowledge human-based climate change, [some of their core beliefs contradict the evolutionary theories](#) that my colleagues and I employ as scientists. But we need not agree about fossils to wean the world off fossil fuels.

The same goes for priorities and economic interests.

A recent [national Pew survey](#) found that a large majority of Americans support the development and use of renewable energy. This includes a slight majority of Republicans, though [their motives tend to differ](#) from those of Democrats.

Republicans are more likely to [prioritize the economic benefits](#) of renewable energy than Democrats, who tend to list global warming as their driving concern.

The economic benefits could explain why [red states produce the largest share of America's wind energy](#) and why three of these states are among the nation's top five producers of solar energy. Their adoption correlates with the geography of the wind and sun belts, where farmers see favorable returns for producing power and a stable source of income to buffer the price fluctuations of weather-sensitive crops. Livelihood is a powerful motivator.

## **Finding common ground could change the world**

None of these examples address climate change on all its fronts. And among Democrats as well as Republicans, there are different opinions about how fast and how far the [transition to renewable energy](#) should go.

But we can take another hopeful lesson from the 19th century: Although people did not agree on all disease-preventing actions, they nevertheless found enough common ground to achieve [the greatest mortality decline in recorded history](#).
